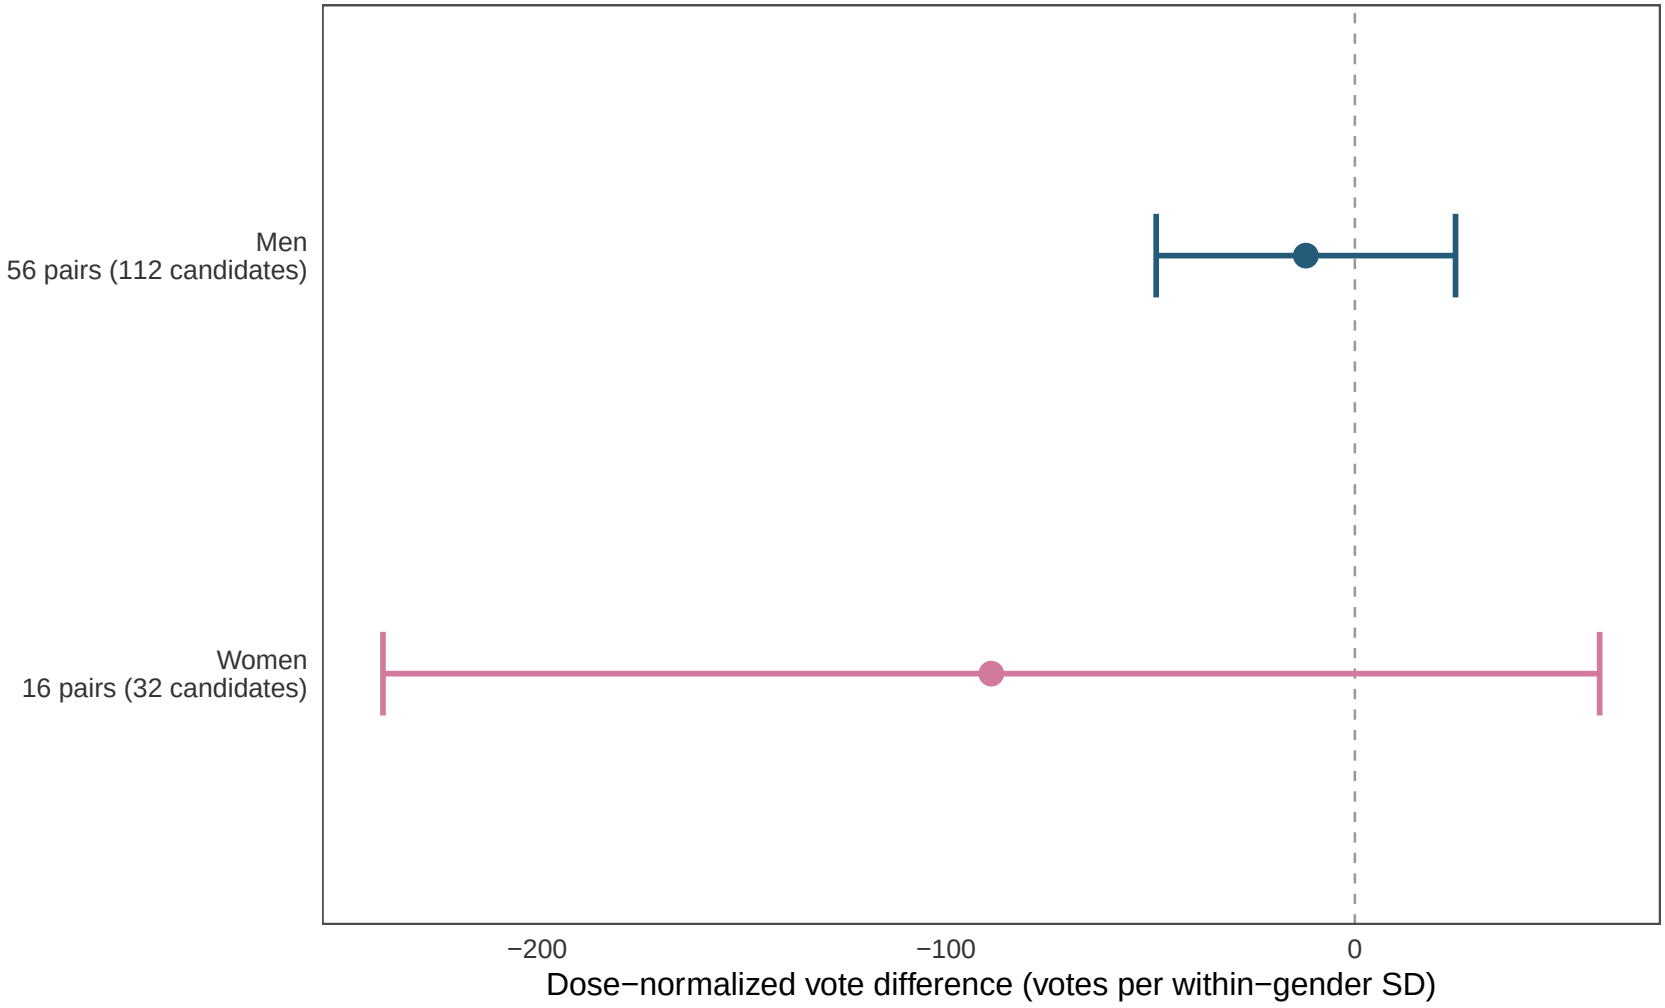
Gender−atypical appearance and personal votes

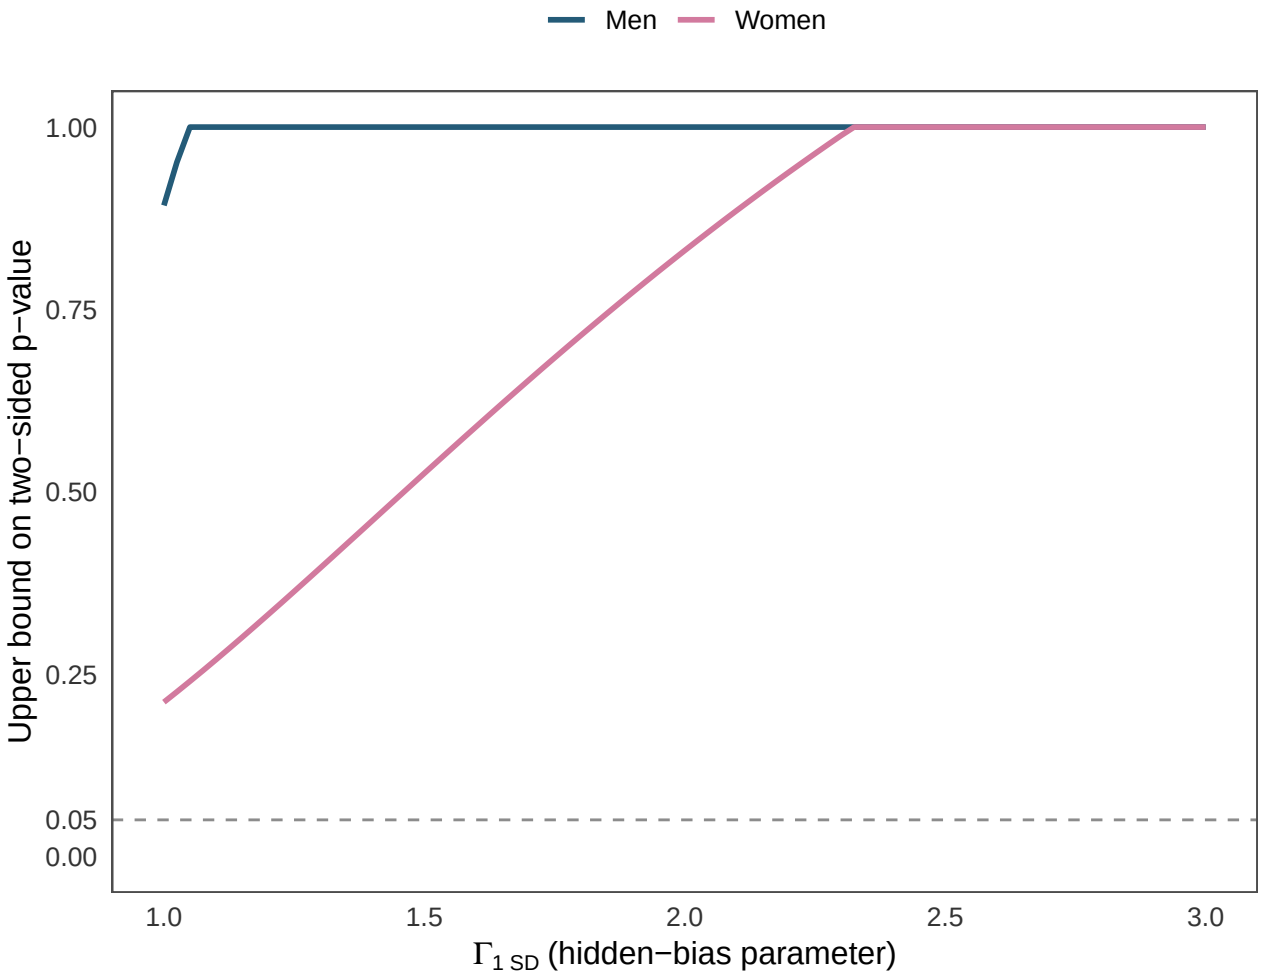
Local contrasts from matched male and female candidates



Dots show within−pair dose contrasts. Bars show approximate 95% Neyman intervals.
Estimates apply to retained candidates over their observed dose differences.
Causal interpretation assumes as−if random dose assignment within matched pairs.

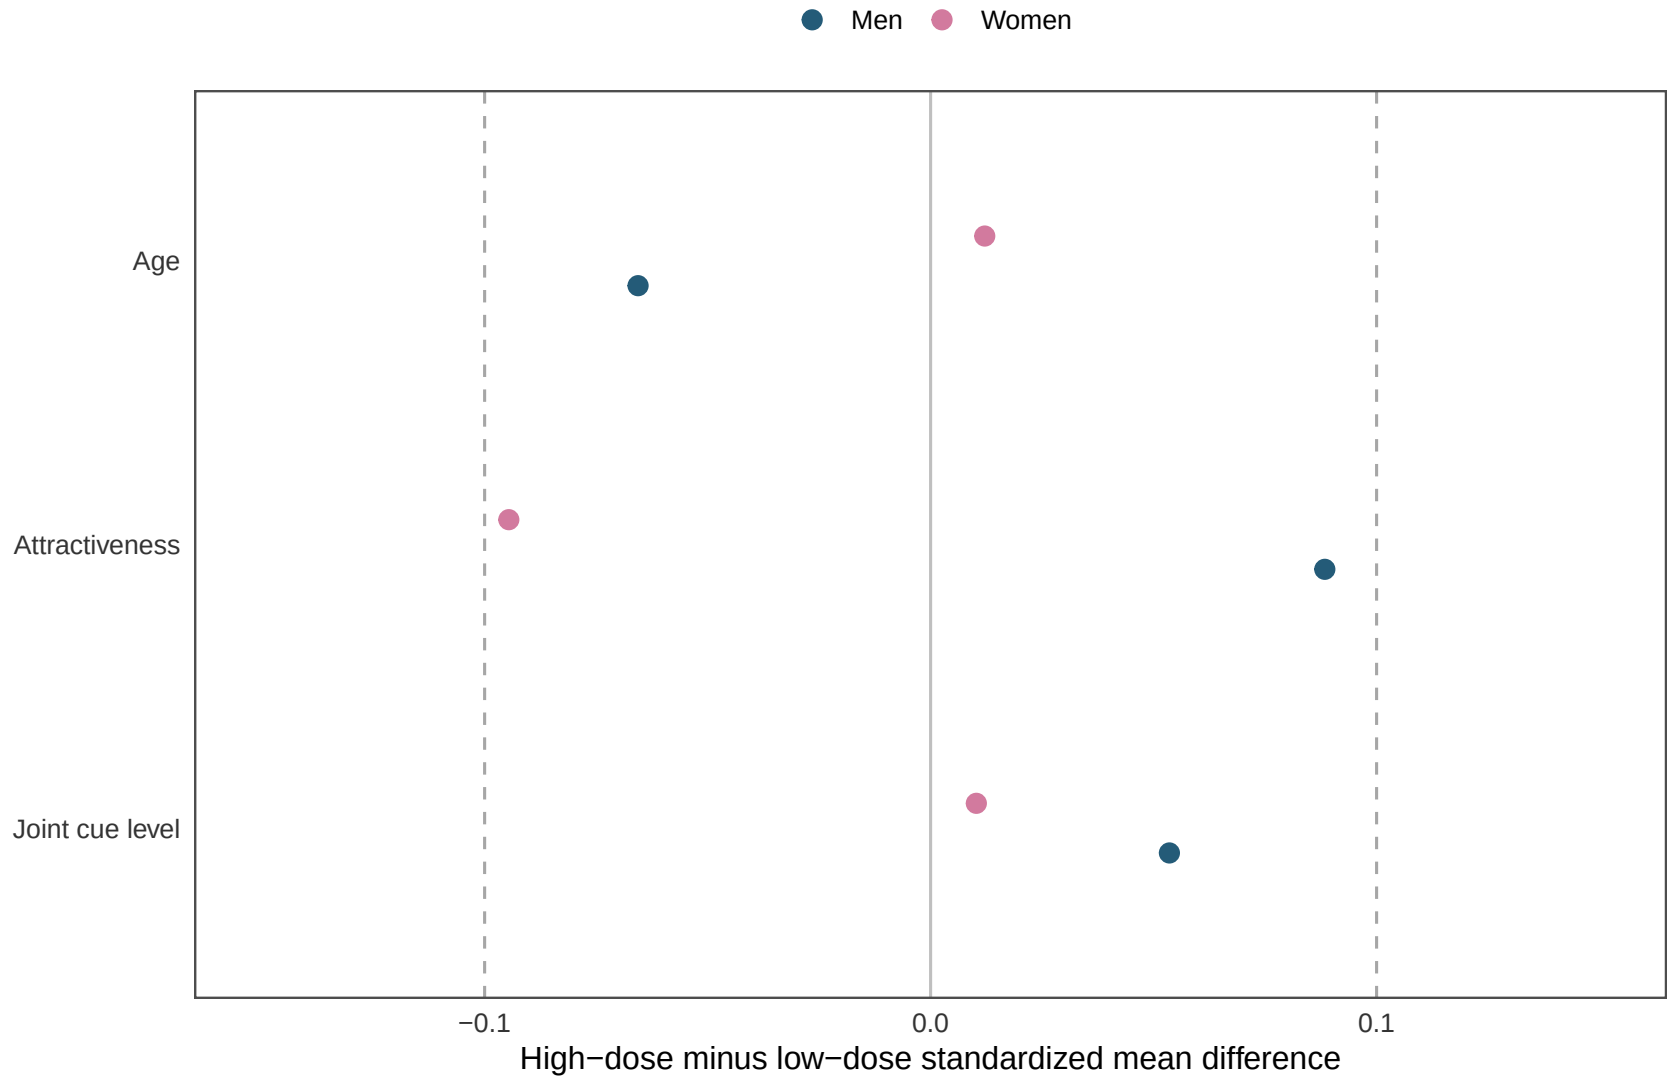
Sensitivity to hidden assignment bias

Exact signed−rank randomization calculation with dose−aware bounds



Gamma = 1 assumes fair within−pair dose assignment. Larger values allow hidden bias.
Each pair's allocation−odds bound is Gamma raised to its actual A−dose gap.
The dashed line marks p = 0.05. The test concerns a sharp null of no dose effects.

Covariate balance after matching



Municipality, party, incumbent status and parliamentary office are matched exactly.
