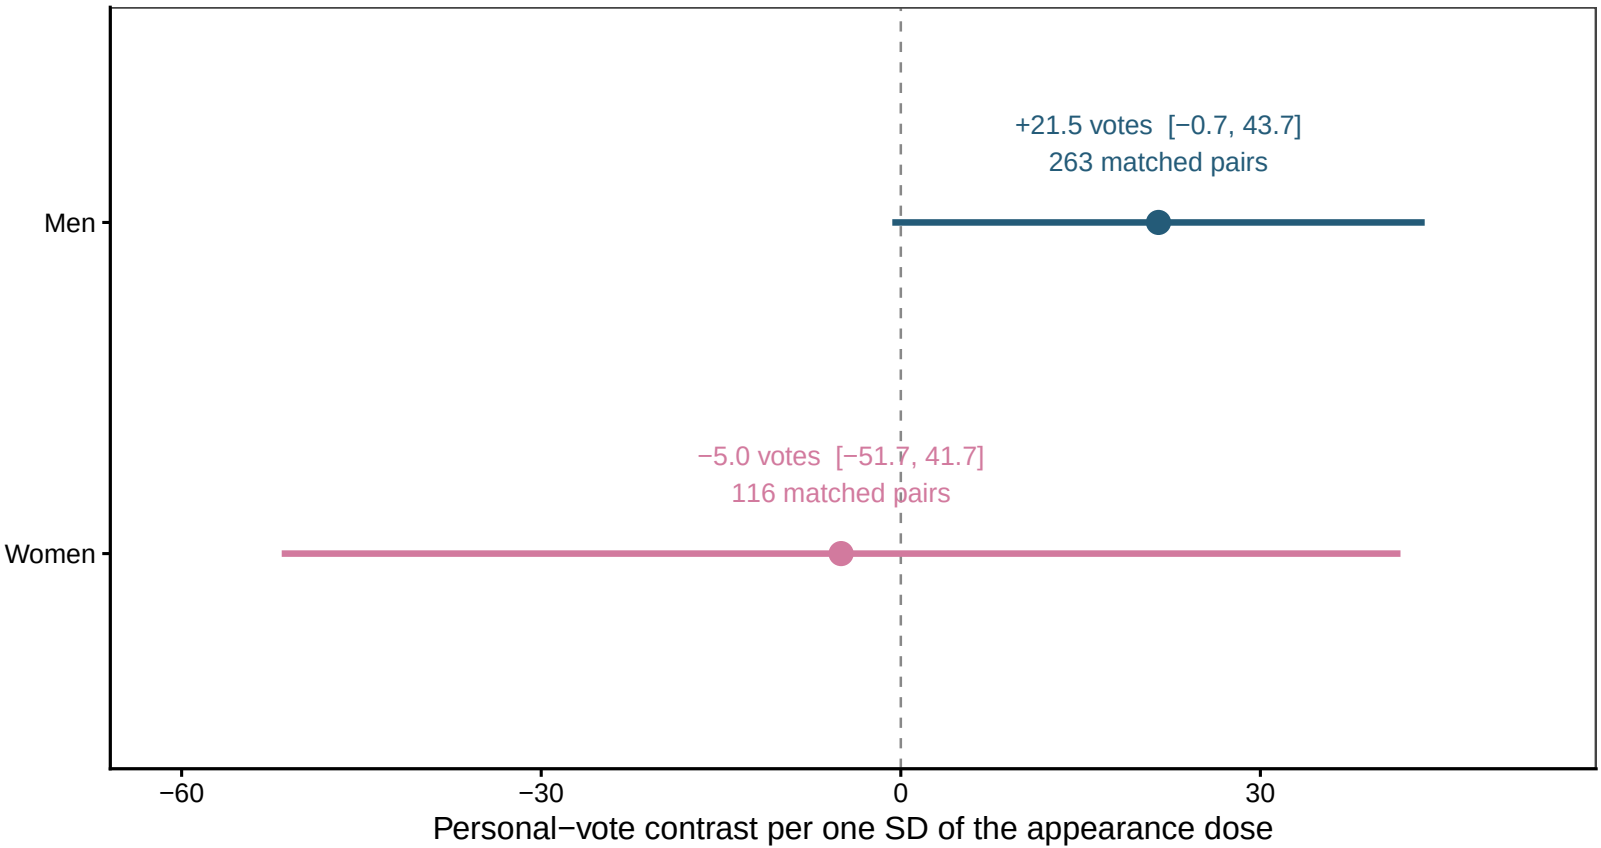
Propensity−score matched appearance contrasts

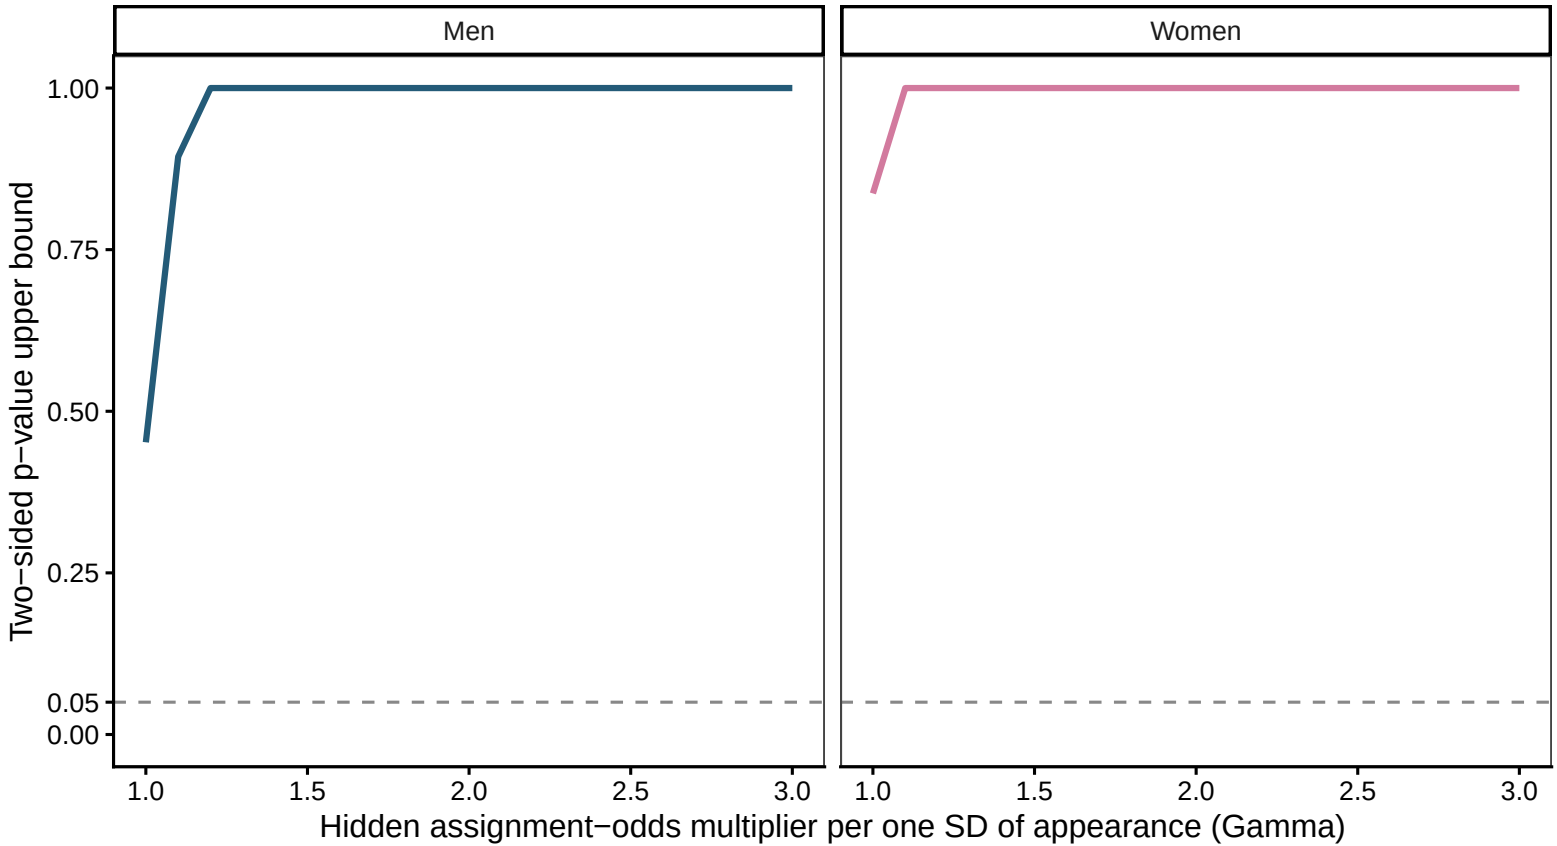
Higher gender−atypical cues versus lower cues among comparable candidates



Dots show continuous−dose matched estimates. Bars show approximate 95% Neyman intervals.
Scores and pairs are fixed before vote outcomes enter the analysis. Men and women are matched separately.
A causal interpretation requires conditional exchangeability and the working dose−assignment model.

Sensitivity to hidden differences between candidates

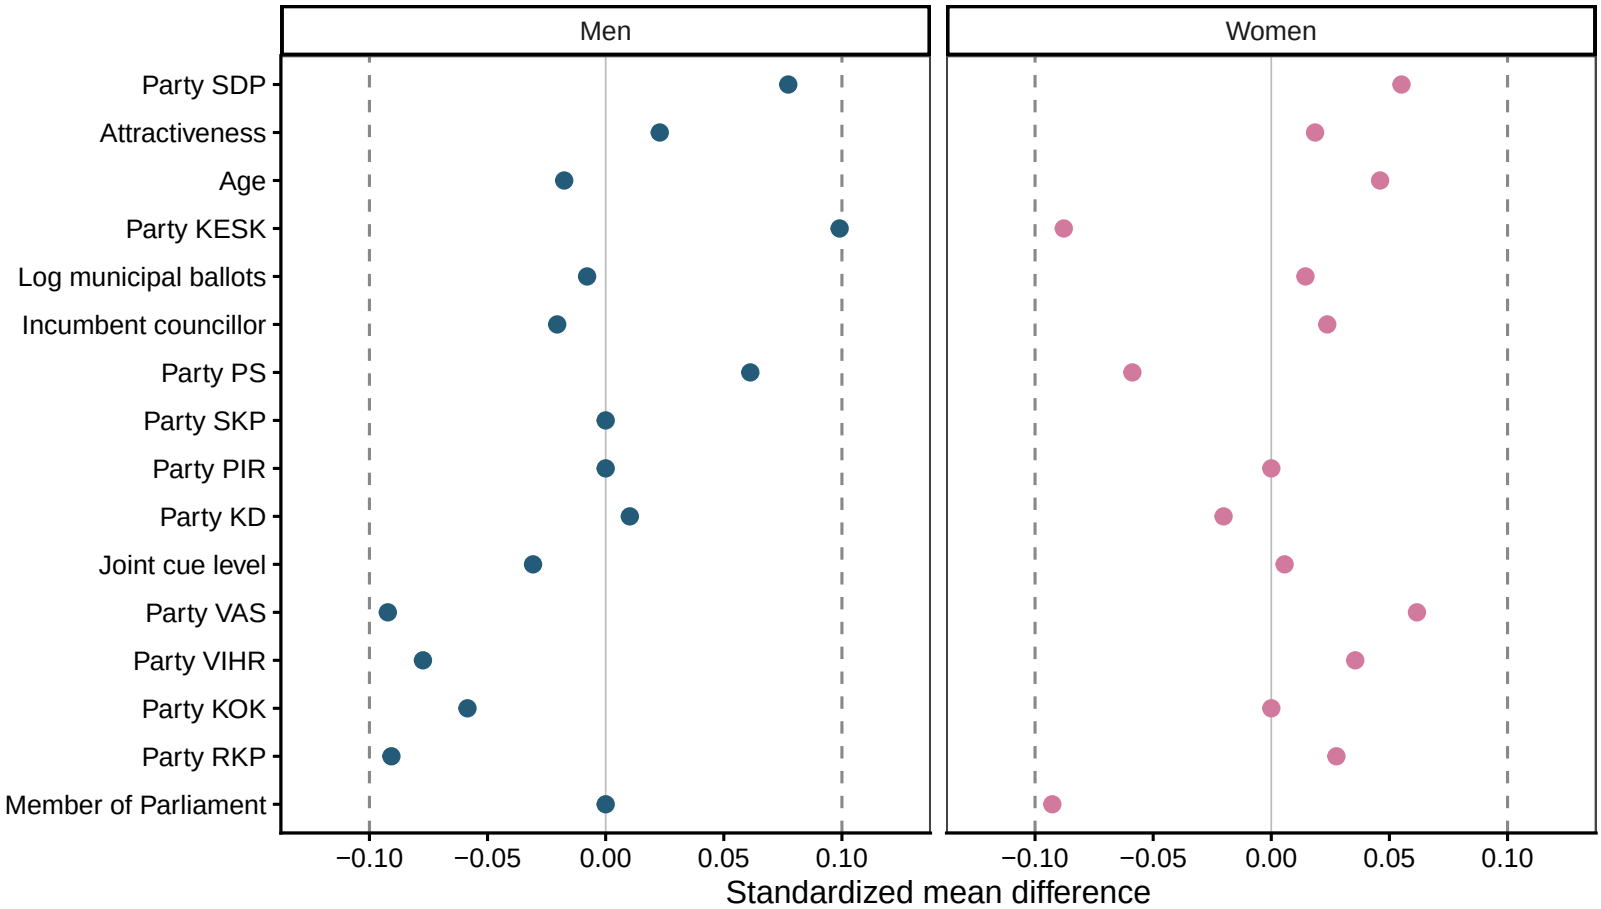
Exact signed−rank bounds allow for fitted dose−assignment probabilities



Gamma = 1 allows no additional hidden bias beyond the fitted assignment score.
For a pair with dose gap d, hidden assignment odds can change by Gamma^d.
The dashed line marks .05. These bounds test a sharp dose−swap null, conditional on the selected pairs.

Balance after propensity−score matching

Higher−dose minus lower−dose candidates



Every score−model covariate and party indicator is within 0.10 full−gender−sample SDs.
